### **Abstract**

Two inequalities well known in the rough set theory have been modified to become equalities by using certain increment operator and uncertain decrement operator, which introduced in our previous papers. The union, intersection, complement operations have also been defined based on the equalities. Boolean algebra property can be satisfied based on these operations. Hence, many properties in rough set theory are improved and the applications of rough set theory are extended. In this paper, we will discuss the properties of certain increment operator farther in rough set data analysis (RSDA), and get some interesting and useful theorems. These theorems will extend the concept of reduct and the generation of reduct algorithm in RSDA. Particularly, a hierachical reduct algorithm (HRA) has been introduced to find the optimal reduct for huge information system. **Keyword**: Certain Increment Operator; Rough Set; Data Analysis.

## **I. Introduction**

In 1982, Z. Pawlak. introduced the rough set theory [1], which has emerged as another major mathematical tool for modeling the vagueness presented in human classification mechanism [8-10]. After more than 20 years' development in this field, rough set theory has been successfully applied in machine learning, pattern recognition, decision support systems, expert systems, data analysis, data mining and so on [2,7]. In reference [3], we have defined certain increment operator and uncertain decrement operator, which can modify inequalities  $R(X \cup Y) \supseteq R X \cup RY$  and  $\overline{R}(X \cap Y) \subseteq \overline{R}X \cap \overline{R}Y$  into equalities, based on which we can redefine the algebraic operation of rough sets, discuss the properties of rough sets, and prove the Boolean algebra of rough sets. In this paper we will discuss the properties of certain increment operator further. Some useful theorems will be established. More important, a hierachical reduct algorithm (HRA) is proposed.

#### **II. Basic Concepts and Properties**

In this section, we will review the definitions and properties of certain increment operator, uncertain decrement operator in reference [3], and some basic concepts of rough set data analysis [1,2]. **Definition 1:** Let *U* be the universe and *R* be an equivalence relation on *U*. For any  $X \subseteq U$  and  $x \in X$ , the two sets

$$
h_X(x) = \{ y \mid y \in [x]_R \land y \notin X \} = [x]_R - X ,
$$
  
\n
$$
l_X(x) = \{ y \mid y \in [x]_R \land y \in X \} = [x]_R - h_X(x) ,
$$
  
\n(1)

are called the basic factor of inducing rough and the correlation basic factor of inducing rough of *X*, respectively.

**Definition 2:** Let *U* be the universe and *R* be an equivalence relation on *U*. For any  $X \subseteq U$  and  $x \in X$  the two sets

$$
H(X) = \bigcup_{x \in Bn_R(X)} h_X(x),
$$
  

$$
L(X) = \bigcup_{x \in Bn_R(X)} l_X(x),
$$

are called *R*-inducing rough region and *R*-inducing rough correlation region of *X*, respectively. **Definition 3:** Let *U* be the universe and *R* be an equivalence relation on *U*. Let *X*,  $Y \subseteq U$ . When *X* is extended by *Y* (i.e.  $X \cup Y$ ),  $\underline{Z_{(.)}}(\cdot): U \times U \rightarrow U$  is defined by

$$
\underline{Z}_X(Y) = \bigcup \{ [x]_R \mid x \in L(X), l_X(x) \subset Y, h_X(x) \subseteq Y \} . \tag{2}
$$

 $\underline{Z}_{\langle \cdot \rangle}(\cdot)$  is called the certain increment operator.

**Definition 4:** Let *U* be the universe and *R* be an equivalence relation on *U*. Let *X*,  $Y \subseteq U$ . When *X* is cut by *Y* (i.e.  $X \cap Y$ ),  $\overline{Z}_{\langle \cdot \rangle}(\cdot): U \times U \to U$  is defined by

$$
\overline{Z}_X(Y) = \bigcup \{ [x]_R \mid x \in L(X), \ l_X(x) \cap Y = \phi, \ h_X(x) \cap Y \neq \phi \}. \tag{3}
$$

 $\overline{Z}_{\alpha}(\cdot)$  is called the uncertain decrement operator.

**Definition 5:** Let *U* be the universe and *R* be an equivalence relation on *U*. Let *X*,  $Y \subseteq U$ . We have  $R(X \cup Y) = R X \cup R Y \cup Z_X(Y)$ 

 $\overline{R}(X \cap Y) = \overline{R}X \cap \overline{R}Y - \overline{Z}_X(Y)$ 

**Definition 6:** Let  $S = \{U, A, V_a, f\}$  be an information system, where *U* is a non-empty finite set of objects, called universe, the elements in *U* are called records. *A* is the attribute set of *S*,  $\forall a \in A$ , *V<sub>a</sub>* is the value set of attribute *a*,  $f: U \times A \rightarrow V$  is called information function. If  $A = C \cup D$ , *C* and *D* are called the condition attribute and decision attribute respectively. When  $C \cup D = A$  and  $C \cup D = \emptyset$ , information system *S* is also called decision system and is expressed by a decision table.

**Definition 7:** Let  $S = \{U, C \cup D, V_a, f\}$  be a decision system, any subset of attribute  $B \subseteq C$ , we define equivalence relation  $IND(B)$  as  $IND(B) = \{(x, y) \in U \times U, \quad a(x) = a(y), \forall a \in B\}$ , which is also called indiscernibility relation.

**Definition 8:** Let  $S = \{U, C \cup D, V_a, f\}$  be an information system, if  $X \subseteq U$ ,  $B \subseteq A$ ,  $\underline{B}(X) = \{x \in U | [x]_B \subseteq X\}, \overline{B}(X) = \{x \in U | [x]_B \cap X \neq \emptyset\}$  will denote the lower and upper approximation of *X* with respect to attribute set *B*, respectively.  $POS_B(D) = \bigcup_{X \in U}$  $(X)$ *X* ∈*U* / *D*  $B(X)$  $\bigcup_{e \cup /D} \underline{B}(X)$  is the positive region of *D* with

respect to *B* .

**Definition** 9: Let  $S = \{U, C \cup D, V_a, f\}$  be an information system, if  $B \subseteq C$ , and for  $\forall r \in B$ ,  $POS_{B}(D) \neq POS_{B-(r)}(D)$ , then *B* is independent; if *B* is independent and  $POS_{B}(D) = POS_{C}(D)$ , then *B* is a reduct of *C*, denoted by  $RED(C)$ .

Obviously, the reduct of *C* is not exclusive. The reducts that have the least attributes are called the minimal reduct or the optimal reduct. The attributes in all reducts of *C* are called the core attributes, denoted by  $CORE(C) = \bigcap RED(C)$ .

# **III. The Discussion of Certain Increment Operator in Rough Set Data Analysis**

The key part of rough set data analysis is the core and reduct of rough set, which is also the main means and approaches to apply rough set to the data mining and knowledge discovering. In this part, we will discuss the performance of certain increment operator in rough set data analysis.

Let  $S = \{U, C \cup D, V, f\}$  be an information system, *C* be a condition attribute set and *D* be a decision attribute set.  $U/C = \{X_1, X_2 \cdots X_k\}$ ,  $U/D = \{Y_1, Y_2 \cdots Y_l\}$ .

If  $C_0 \subseteq C$ ,  $U/C_0 = \{Z_1, Z_2, \dots, Z_N\}$ , information system  $S_i = \{Z_i, (C - C_0) \cup D, V_a, f\}$  ( $i = 1, 2 \dots N$ ) is called an information subsystem of information system *S* with respect to  $C_0$ .

We will introduce three lemmas before discussing further the theorems of certain increment operator.

**Lemma 1:** Supposing that attribute set  $B \subseteq A$ ,  $\forall x, y \in U$ , if  $[x]_B \neq [y]_B$ , then  $[x]_A \neq [y]_A$ .

**Lemma 2:**  $\forall x, y \in U$ , if  $[x]_A \neq [y]_A$ , then  $[x]_A \cap [y]_A = \phi$ .

**Lemma 3:** If attribute sets  $A \subseteq B \subseteq C$ , and  $POS_A(D) = POS_C(D) = M$ , then we have  $POS_B(D) = M$ .

**Theorem 1:** If attribute sets  $C_0 \subseteq C$ ,  $B \subseteq D$ ,  $Y_i \in U/B$ ,  $Y_i/C_0 = \{Y_{i1}, Y_{i2}, \dots, Y_{i_m}\}\$ ,  $i = 1, 2 \dots l$ , then  $Z_{Y_i}(Y_{i_j}) = \emptyset$ , where  $u, v \le m$ ,  $u \ne v$ .

**Proof.**  $Y_i/C_0 = \{Y_{i1}, Y_{i2}, \dots Y_{i_m}\}\$ , hence  $\forall x_s \in Y_{iu}, x_t \in Y_{iv}\$ ,  $u, v \leq m$ , and  $u \neq v$ ,  $[x_s]_{C_0} \neq [x_t]_{C_0}\$ . From lemma 1, we have  $[x_s]_c \neq [x_t]_c$ . From lemma 2, we can get  $[x_s]_c \cap [x_t]_c = \phi$ . For the randomicity of *t*, we can obtain  $[x_s]_c \bigcap Y_{i\nu} = \phi$ . According to definition 1.1,  $h_{Y_{i\nu}}(x_s) \subseteq [x_s]_c$ . Hence  $h_{Y_{i\nu}}(x_s) \bigcap Y_{i\nu} = \phi$ . Moreover, according to definition 1.3,  $Z_{Y_i}(Y_i) = \phi$ .

This theorem indicates that in rough set data analysis, if the definition region of certain increment operator is the equivalence class of the universe *U* with respect to decision attribute set *D*, then certain increment operator equals zero. In such case, we have the following theorem.

**Theorem 2:** Supposing that attribute set  $C_0 \subseteq C$ ,  $Y_i \in U/D$ ,  $Y_i/C_0 = \{Y_{i1}, Y_{i2}, \dots, Y_{i m}\}$ ,  $i = 1, 2 \dots l$ , then  $\underline{C}(Y_{i\alpha} \cup Y_{i\nu}) = \underline{C}(Y_{i\alpha}) \cup \underline{C}(Y_{i\nu})$ .

**Proof.** According to theorem 1,  $Z_{y_i}(Y_i) = \phi$  ( $u, v \leq m$ ,  $u \neq v$ ). From definition 1.5, we can get  $\underline{C}(Y_{i\alpha} \cup Y_{i\alpha}) = \underline{C}(Y_{i\alpha}) \cup \underline{C}(Y_{i\alpha}).$ 

**Inference:** If attribute set  $C_0 \subseteq C$ ,  $Y_i \in U/D$ ,  $Y_i/C_0 = \{Y_{i1}, Y_{i2}, \dots Y_{im}\}$ , then  $\underline{C}(Y_i) = \bigcup_{Y_{i\mu} \in U/C_0} \underline{C}(Y_{i\mu})$  $\sum_{Y_{iu} \in U/C_0} \underbrace{\cup (I_{iu})}$  $C(Y_i) = \begin{bmatrix} \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot \end{bmatrix}$  $=\bigcup_{Y_{iu}\in U/C_0} \underline{C}(Y_{iu})$ .

**Theorem 3:** If attribute set  $C_0 \subseteq C$ ,  $Y_i \in U/D$ ,  $Y_i/C_0 = \{Y_{i1}, Y_{i2}, \dots, Y_{i m}\}$ ,  $i = 1, 2 \dots l$ , then  $POS_{C}(D)=POS_{C}(D\bigcup C_{0})$ .

**Proof.** From the inference,  $\sqrt{C_0}$  $(Y_i) = \begin{bmatrix} \end{bmatrix} C(Y_{i\omega})$  $Y_i = \bigcup_{Y_{iu} \subseteq U/C_0} \subseteq (I_{iu})$  $C(Y_i) = \begin{bmatrix} \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot \end{bmatrix}$  $=\bigcup_{Y_u \subseteq U/C_0} \underline{C}(Y_u)$ , hence,  $POS_C(D) = \bigcup_{Y_i \in U/D} \underline{C}(Y_i)$  $\sum_{Y_i \in U/D} \leq (I_i)$  $POS_{C}(D) = \left[ \begin{array}{cc} C(Y) & C(Y) \end{array} \right]$  $=\bigcup_{Y_i\in U/D}\underline{C}(Y_i)$  =  $\langle DY_{iu} \in Y_i / C_0$  $(Y_{\scriptscriptstyle in})$  $\bigcup_{Y_i \in U/DY_{iu} \in Y_i/C_0} \subseteq \mathcal{C}$ *iu*  $C(Y_i)$  $\bigcup_{i \in U/DY_{iu}} \bigcup_{i \in V_i/C_0} \underline{C}(Y_{iu}) = \bigcup_{Y_{iu} \in U/(D \cup C_0)} \underline{C}(Y_{iu})$  $Y_{iu} \in U / (D \cup C_0)$ <sup> $C$ </sup>  $C(Y)$  $\bigcup_{v \in U/(D \cup C_0)} \underline{C}(Y_{uv}) = POS_C(D \cup C_0)$ .

**Theorem 4:** In an information subsystem  $S_i$ , for any  $x \in Z_i$ , we have  $[x]_{C-C_i} = [x]_C$ .

**Proof.** Since  $C - C_0 \subseteq C$ , we have  $[x]_C \subseteq [x]_{C-C_0}$ .

For any  $x, y \in [x]_{C-C}$ ,  $\forall c \in C-C_0$ , we have  $c(x) = c(y)$ . Furthermore,  $x, y \in Z_i$ , we have  $c'(x) = c'(y)$ ,  $\forall c' \in C_0$ . Therefore for any  $c \in C$ , we can obtain  $c(x) = c(y)$ , then  $x, y \in [x]_C$ , i.e.  $[x]_{C-C_0} \subseteq [x]_C$ . So  $[x]_{C-C_0} = [x]_{C}.$ 

**Theorem 5:** In information subsystem  $S_i$ , for any  $Y_i \in Z_i/D$ , we can get  $C - C_0(Y_i) = \underline{C}(Y_i)$ .

**Proof:** According to the definition of lower approximation and theorem 4,  $C - C_0(Y_j) = \{x \mid x \in Z_i, [x]_{C-C_0} \subseteq Y_j\} = \{x \mid x \in Z_i, [x]_{C} \subseteq Y_j\} = \underline{C}(Y_j)$ .

**Theorem 6:** If the positive region of information subsystem  $S_i$  is  $POS_{C-C_0}(D)$ , then  $\mathfrak{c}$   $-\mathfrak{c}_0$  $(i)$  $(D)$  $\bigcup_{Z_i \in U/C_0} POS_{C-C_0}^{(i)}(D) = POS_C(D)$ .

*i* **Proof.**  $\bigcup_{Z_i \in U/C_0} POS_{C-C_0}^{(i)}$  $(i)$ /  $(D)$ *i*  $\bigcup_{Z_i \in U/C_0} POS_{C-C_0}^{(i)}(D) = \bigcup_{Z_i \in U/C_0} \bigcup_{Y_j \in Z_i/D} \underbrace{C-C_0}_{D}$  $(Y_i)$  $\bigcup_{Z_i \in U/C_0} \bigcup_{Y_j \in Z_i/D} \underbrace{C - C_0}_{U} (I_i)$  $C - C_0(Y)$  $\bigcup_{i \in U / C_0} \bigcup_{Y_j \in Z_i / D} C - C_0(Y_i) = \bigcup_{Y_j \in U / (D \cup C_0)} \underline{C}(Y_i)$  $\bigcup_{Y_j \in U} \bigcup_{\langle (D \cup C_0) \rangle} \subseteq (I_i)$  $C(Y)$  $\bigcup_{i \in U/(D \cup C_0)} \underline{C}(Y_i) = POS_C(D \cup C_0) = POS_C(D)$ .

**Theorem 7:** Let  $C_i$  be a reduct of the information subsystem  $S_i$ , then  $\bigcup_{Z_i \in U/C_0} POS_{\lambda C_i}^{(i)}$  $\bigcup_{Z_i \in U/C_0} POS_{\kappa C_i}^{(i)}(D) = POS_C(D)$ , *i*

where  $\land$ *C<sub>i</sub>* denote the conjunction of *C<sub>i</sub>*.

/

**Proof.** If  $C_i$  is a reduct of information subsystem  $S_i$ , then  $POS_{C-C_0}^{(i)}(D) = POS_{C_i}^{(i)}(D)$ . For any  $C_i$ , we have  $C_i \subseteq \wedge C_i \subseteq C - C_0$ . According to lemma 3, we know  $\bigcup_{Z_i \in U/C_0} POS_{C_i}^{(i)}(D) = \bigcup_{Z_i \in U/C_0}POS_{C_0}^{(i)}(D)$  $\bigcup_{i \in U/C_0} POS_{C_i}^{(i)}(D) = \bigcup_{Z_i \in U/C_0}POS_{\wedge_{C_i}}^{(i)}(D)$  $\bigcup_{Z_i \in U/C_0} POS_{C_i}^{(i)}(D) = \bigcup_{Z_i \in U/C_0}POS_{\wedge_{C_i}}^{(i)}(D)$ . From theorem 6, we have  $\bigcup_{Z_i \in U/C_0} POS_{C-C_0}^{(i)}$  $(i)$ /  $(D)$ *i*  $\bigcup_{Z_i \in U/C_0} POS_{C-C_0}^{(i)}(D) = \bigcup_{Z_i \in U/C_0}POS_{C_i}^{(i)}$  $\bigcup_{i\in U/C_0} POS_{C_i}^{(i)}(D)$  $\bigcup_{Z_i \in U/C_0} POS_{C_i}^{(i)}$  $POS_{C}^{\left( i\right) }(D% \mathbb{R})=\left( \begin{array}{c}% \left( \Delta\right) ^{\left( i\right) }&i\in\mathbb{Z}\ \end{array} \right)$  $\bigcup_{i \in U/C_0} POS_{C_i}^{(i)}(D) = \bigcup_{Z_i \in U/C_0}POS_{C_i}^{(i)}$  $\bigcup_{\zeta_i \in U \, \wedge \, \mathcal{C}_0} POS_{\wedge_{\mathcal{C}_i}}^{(i)}\left(D\right)$ *i*  $\bigcup_{Z_i \in U/C_0} POS_{\wedge_{C_i}}^{(i)}(D) = POS_C(D)$ .

**Remark:** From the definition of reduct, we know that reduct is a set of some attributes. However, from the viewpoint of discernibility matrix, reduct is the conjunction of some attributes. This paper has used both of the two points of view, but it's not difficult to distinguish them according to context. Thus, in this paper, we use the same expression of reduct, without distinguishing whether it express a set or a conjunction form.

**Theorem 8:** Let  $C_i$  be a reduct of information subsystem  $S_i$ . If  $C_0$  is the core of information system *S*, then  $C_0 \bigcup (\wedge C_i)$  is a reduct of information system *S*.

**Proof.** To prove that  $C_0 \cup (\wedge C_i)$  is a reduct of information system *S*, we only need to prove two conditions: 1) 0  $(i)$  $\bigcup_{i \in U/C_0} POS_{\lambda C_i}^{(i)}(D) = POS_C(D)$  $\bigcup_{Z_i \in U/C_0} POS_{\scriptscriptstyle \wedge C_i}^{(i)}(D) = POS_{C}(D) \ ; \ \ 2) \quad \forall r \in ( \wedge C_i ) \ , \ \bigcup_{Z_i \in U/C_0}POS_{\scriptscriptstyle \wedge C_i}^{(i)}$  $\bigcup_{i \in U/C_0} POS_{\scriptscriptstyle \wedge C_i-r}^{(i)}(D) \neq POS_C(D)$  $\bigcup_{z_i \in U/C_0} POS_{\lambda C_i-r}^{(i)}(D) \neq POS_C(D)$ . As  $C_0$  is the core of information system S, the element of  $C_0$  can not be taken out. 1) has been proven by theorem 7, we will prove 2). ∀ $r \in ( \land C_i )$ , so there would exist at least one  $C_i$ , and  $r \in C_i$ . If *r* is taken out from  $\wedge C_i$ , according to the definition of reduct, we have  $POS_{C_i}^{(i)}(D) \neq POS_{C_{i-r}}^{(i)}(D)$ , i.e.  $POS_{\wedge C_i}^{(i)}(D) \neq POS_{C_{i-r}}^{(i)}(D)$ . Hence,  $\bigcup_{Z_i \in U/C_0} POS_{\wedge C}^{(i)}$ /  $\bigcup_{j\in U/C_0} POS_{\wedge C_j}^{(i)}(D)$  $\bigcup_{Z_i \in U/C_0} POS_{\wedge C_i}^{(i)}(D) \neq \bigcup_{Z_i \in U/C_0}$  $(i)$  $\bigcup_{i \in U/C_0} POS_{C_i-r}^{(i)}(D)$  $\bigcup_{Z_i \in U/C_0} POS_{C_i-r}^{(i)}(D)\text{ , i.e. }\bigcup_{Z_i \in U/C_0}POS_{\scriptscriptstyle \wedge C_i}^{(i)}$  $\bigcup_{i \in U/C_0} POS_{\lambda C_i-r}^{(i)}(D) \neq POS_{C}(D)$  $\bigcup_{Z_i \in U/C_0} POS_{\lambda C_i-r}^{(i)}(D) \neq POS_C(D)$ . So,  $C_0 \bigcup (\wedge C_i)$  is a reduct of

information system *S*.<br>**Theorem 9:** Let  $C_i$  be the minimal reduct of information subsystem  $S_i$ , then the minimal reduct of information system will need max $\{ |C_i| \}$  attributes, on the basis of attribute set  $C_0$ , denoted as  $ZX(S)$ , where  $|C_i|$  denotes the number of attributes in  $C_i$ .

**Proof.** According to theorem 8, the reduct of information system can be denoted as  $C_0 \cup (\wedge C_i)$ . For any  $C_i$ , there is  $|C_i| \leq |\Lambda C_i|$ . Hence, the minimal reduct of information system will need at least  $max\{|C_i|\}$  attributes, on the basis of attribute set  $C_0$ .

**Theorem 10:** Let  $\{C_{ij}, j = 1, 2 \cdots r_i\}$  be all the minimal attribute reducts of information subsystem *S<sub>i</sub>*; *r<sub>i</sub>* is the number of the minimal attribute reducts,  $C_{ij}$  denotes the *j*-th the minimal attribute reduct of information subsystem  $S_i$ . We can construct discernibility function  $\bigwedge_{S_i \in \mathcal{S}} \bigvee_{j=1}^{I_i} C_{ij}$ *i r*  $\sum_{S_i \in IS} (\bigvee_{j=1}^{i} C_{ij})$  on the basis of  ${C_{ii}, j=1,2 \cdots r_i}$ . According to the discernibiliy function we construct the conjunction normal forms,

Pinjia Zhang, and Hongli Lian

The Discussion of Certain Increment Operator in Rough Set Data Analysis

denoted by  $B_k$ ,  $k = 1, 2, \dots, n$ . Then the minimal attribute reduct of information system *S* will still need  $min(|B_k|)$  attributes at most, on the basis of attribute set  $C_0$ , denoted as *ZD(S)*.

**Proof.** As  $B_k = \wedge C_{ij}$ ,  $C_{ij}$  is a minimal attribute reduct of information subsystem  $S_i$ . From theorem 8, we know  $C_0 \cup B_k$  is a reduct of information system *S*. Moreover,  $|C_0 \cup B_k| \geq |C_0| + \min |B_k|$ ,  $k = 1, 2, \dots, n$ , thus the minimal attribute reduct of information system *S* will still need min( $|B_k|$ ) attributes, on the basis of attribute set  $C_0$ .

**Theorem 11:** If *B* is a reduct of information system *S*, and  $|B| \le ZD(S) + |C_0|$ , then there must be a  $C_i$ ,  $| C_i | \le ZD(S)$ , so that  $B = C_0 \cup (\wedge C_i)$ .

**Proof.** As *B* is a reduct of information system *S*, there must be  $C_i \subseteq B$ , which is a reduct of information subsystem *S<sub>i</sub>*. In addition,  $|B| \leq ZD(S) + |C_0|$  and  $C_0 \subseteq B$ , we have  $|C_i| \leq ZD(S)$ . Hence  $C_0 \cup (\land C_i) \subseteq B$ . As  $C_i$  is a reduct of information subsystem  $S_i$ , according to theorem 8,  $C_0 \cup (\land C_i)$  is a reduct of information system *S*. From the definition of reduct, we can obtain  $C_0 \bigcup (\wedge C_i) = B$ .

# Ⅳ**. The Minimal Reduct Algorithm Based on HAR**

The information system based on rough set can be separated into information system with decision (DIS) and information system without decision (NDIS). Computing the reduct of NDIS is to obtain the minimal attribute set who can distinguish the records according to information system, the basis of which is maintenance indiscernibility. The purpose of computing the reduct of DIS is to obtain the most simplified decision. The basis of the computing the reduct of NDIS is the rule of compatibility. If we consider the attribute set of NDIS as the decision set of DIS, then NDIS can be considered as DIS, thus we deal with DIS only in this paper. According to whether or not having core, the information system based on rough set can be separated into core-information system (CIS) and norcore-information system (NCIS). We will discuss them respectively as following.

#### *A. The Minimal Reduct Algorithm of CIS*

Let  $S = (U, C \cup D, V_a, f)$  is a information system, where  $U = \{x_1, x_2, \dots, x_n\}$  is universe; *C* is the condition attribute set, *D* is the decision attribute set,  $V_a$  is the set constructed by all attribute values,  $f :$  $U \rightarrow V_a$  is the information function.

The process of the minimal reduct of CIS is as follows:

- 1. To get the core of *S*, denoted by  $C_0$ .
- 2. Classify *U* according to  $C_0$ ,  $U/C_0 = \{Z_1, Z_2, \dots Z_k\}$ . Separate *S* into *k* sub-information systems (SIS)  $S_i = (Z_i, (C - C_0) \cup D, V_a, f)$ ,  $i = 1, 2, \dots k$ , where  $a' \in C - C_0$ .
- 3. Deduce all the reduct of  $S_i = (Z_i, (C C_0) \cup D, V_a, f)$ ,  $i = 1, 2, \dots k$ .
- 4. Use theorem 9 and theorem 10 to get  $ZX(S)$  and  $ZD(S)$ .
- 5. Judge whether or not  $ZX(S)$  equals to  $ZD(S)$ . If they are not equal, then we compute next step. If they are equal, stop. Then the collection of the minimal reduct of *S* is the union of the core and the reduct having *ZX(S)* attributes.
- 6. Select the reducts of  $S_i$ ,  $i = 1, 2, \dots k$ , whose number of attributes is less than *ZD(S)* in step 3, and then use them to construct discernibility function and then solve it. In the process of solving, all conjunction normal forms whose number of elements is greater than  $ZD(S)$  are deleted. Then the collection of the minimal reduct of *S* is the union of the core and the reduct which having the least number of elements in the conjunction normal forms are selected in results.

In step 3, if there is a SIS  $S_i$  which leads  $\forall x_m, x_n \in Z_i$ ,  $\forall d \in D$ , then we have  $d(x_m) = d(x_n)$ , that is to say, there is a  $Y_k \in U/D$ , which leads  $Z_i \subseteq Y_k$ , that is to say that  $Z_i$  relates with  $C_0$  only, and does not relate with  $C - C_0$ . Thus we can suppose that the reduct of  $S_i$  are empty set  $φ$ .

Using this method we can compute the minimal reduct of information system, but they are not all the minimal reducts. If we want obtain all the minimal reducts, we need only get rid of step 5, then change "less than" into "less than or equal to" in step 6.

SIS  $S_i$  is NCIS. Now we use discernibility matrix to prove it. Let  $S_i$  have core. Then there exit two records  $x_u, x_v \in Z_i$ . There is one and only one attribute *a* in  $C - C_0$  that leads to  $a(x_u) \neq a(x_v)$ . And let  $a' \in C - C_0 - \{a\}$ , then  $a'(x_u) = a'(x_v)$ . Because  $Z_i \in U/C_0$ , then  $\forall a_0 \in C_0$ ,  $a_0(x_u) = a_0(x_v)$ . That is, there is only one attribute *a* leads  $a(x) \neq a(x)$ , thus *a* is the core of information system. This is conflict with  $a \in C - C_0$ . So  $S_i$  is NCIS.

Because SIS is NCIS and some information systems are the NCISs, so it is necessary to discuss how to compute the reduct of NCIS.

#### *B. The Minimal Reduct Algorithm of NCIS*

The character of NCIS is that there are many attributes but few records in information system. If NCIS is small, then we can use discernibility matrix to compute the minimal reduct directly. In fact, we can not assure the scale of NCIS does not exceed the applied range of discernibility matrix, and thus under the enlightenment of computing the reduct of CIS, we get the minimal reduct algorithm of CIS.

According to discernibility matrix, the cores of information system are the entries having single attribute in discernibility matrix. Because the relativity positive region will change if we get rid of these entries, thus they must exit in every reduct.

However the entries having multi-attribute in discernibility matrix do not have this character. But there is one attribute at least in every entry having multi-attribute, which is the element of some minimal reduct.

The algorithm for NCIS is as follows:

- 1. To get the discernibility matrix of NCIS.
- 2. Find out a entry that has the least attributes in discernibility matrix.
- 3. Extract every attribute from this entry in return as preparative core, then according to the minimal reduct algorithm of CIS to compute the minimal reduct.
- 4. The reduct having the least number in all the minimal reduct based on every preparative core is the minimal reduct of NCIS.

In the minimal reduct algorithm of CIS, we propose the concept of preparative core. The minimal reduct of information system based on preparative core is equivalent to the minimal reduct of information system based on hypothetic condition, when it is assumed that preparative core exits in the minimal reduct. From the above analysis, we know that this condition is not always satisfied. However, if we extract every attribute in the entry having the least number of attributes in discernibility matrix in return as preparative core, then this condition will be satisfied once at least. That is to say, the results that are computed by step 3 and step 4 in above algorithm must be the minimal reduct.

In CIS, if the SISs is still large, then it will produce data overflow in the process of computing. From above section we know SISs is the NCISs. So it can be separated further by the minimal reduct algorithm of NCIS until it can be computed.

# Ⅴ**. Example**

Take CTR (Car Test Results) database [5] for example. Using the minimal reduct algorithm of CIS proposed in the paper to compute its minimal reduct.

The Discussion of Certain Increment Operator in Rough Set Data Analysis

In CRT database, 10 attributes are given in Table 1: *a*—the whole length, *b*—the number of bicycle pump, *c*—existence of turbocharger, *d*—types of fuel system, *e*—tonnage of engine, *f* compressibility, *g*—power, *h*—types of driver, *i*—weight, *y*—miles.

Attribute values: c—roadlouse, s—mini car, sm—small, y—yes, n—no, E—2-BBL, m—middle, ma—manual, h—high, he—weight, l—light, lo—low, a—auto

Information system is  $S = \{U, C \cup D, V_a, f\}$ , where  $U = \{1, 2, \dots 21\}$ ,  $C = \{a, b, \dots i\}$ ,  $D = \{y\}$ .

- 1. To get core of *S*.  $core(C) = \{d, i\}$ .
- 2. According to { ,} *d i* we separate *S*, *U di* /{ , } ={{1,2,3,5,12,14,16,17,18,19,  $20\{4,11\},\{6\},\{7\},\{8\},\{9,10,13,15,21\}\}\$ . According to theorem 8, we only need to consider SISs constructed by the equivalence class whose records are larger than or equal to 2. In this example, there are 3 equivalence classes whose records larger than 2, mark them  $Z_1, Z_2, Z_3$ respectively. And because all records in equivalence class *Z*, are equal, we only need to consider two SISs  $S_1 = (Z_1, C - \{d, i\}, V_a, f)$  and  $S_6 = (Z_6, C - \{d, i\}, V_a, f)$ .
- 3. The reducts of  $S_1$  are:  $\{a,e\}$ ,  $\{a,f,g\}$ ,  $\{a,b,f\}$ ,  $\{a,b,g\}$ ,  $\{b,e,g\}$ ,  $\{b,f,g\}$ ,  ${b, c, e, h}, {b, c, f, h}, {a, b, c, h}.$

The reducts of SIS  $S_6$  are:  $\{a\}, \{e, f\}, \{f, g\}$ .

4. According to theorem 9, we have *ZX*=2. According to theorem 10, we have  $a \wedge ae = ae$ , *ZD*=2. Thus *ZD*=*ZX*, hence  $\{d, i\} \cup \{a, e\} = \{a, d, e, i\}$  is a minimal reduct of *S*.

If we want to get all the minimal reduct, it need still the reduct whose attributes are lower than or equal to *ZD* in SISs  $S_1$  and  $S_6$  to construct discernibility function  $(a \vee ef \vee fg) \wedge ae = ae \vee aef \vee aefg$ , the reduct whose the number of attributes equal to 2 have only one. Thus, there is only one minimal reduct in *S*, that is  $\{d, i\} \cup \{a, e\} = \{a, d, e, i\}.$

**Table 1.** CRT Information System

From this example we can see that using the concepts of *ZD*, *ZX* to compute the minimal reduct can minish the searching range conspicuously. In this example there are only two SISs. If there are more SISs, then the degree of decrease will be more conspicuously.

# Ⅵ**. Conclusion**

In this paper, we find the condition that the certain increment operator equals zero in the aspect of rough set data analysis and furthermore develop the theory and introduce a algorithm of rough set reduct based on this condition. Firstly, transform the huge information system into smaller manageable information subsystem; secondly, reduce the information subsystem; and lastly, synthesize the results of information subsystem reduct, and obtain the reduct of the huge information system. All of which have been proven sufficiently by the 11 theorems in this paper. We believe that the discussion of certain increment operator is worthwhile, which would propel the development of rough set data analysis theory. However, for some special information system, the users or decision makers may consider some special conditions which lead the minimal reduct is not always necessary for users. For this problem, we will use the idea of hierachical reduct and the concepts of the minimum and the maximum to discuss it according to user's requirement in latter works.
